Introduction

Manufacturing automation is by no means standard in panel building: The percentage of panel builders and mechanical engineers having automation in production is currently 5-10% at the most. Yet with increasing digitalization and integrated data flow above and beyond processes and systems, this will change. Fundamentally. Within ten years, according to experts, 80% of Germany’s panel builders and mechanical engineers will be producing using full or partial automation.

The transformation begins – for example in Computer Aided Engineering (CAE) – with planning in a 3D format. And it leads to machine-controlled production and automation processes, which are running more quickly, more resource-efficient and more precisely than ever before. But first things first ...
In 2010, CAE was still rendering two-dimensional construction diagrams
It wasn't even ten years ago when e-designers were already designing their control cabinets on the computer. The calculation of parts lists per component was already being performed in a CAE system. Three dimensionality, however, was as much a pipe dream as direct data flow from design into production. Instead, software-based creation of a panel building diagram more or less meant generating a two-dimensional drawing. In the end, the plan was printed out and forwarded to the production department. On the basis of the CAE drawing, a separate terminal and wiring diagram was created, indicating how the devices were to be connected to one another in the cabinet.

Today, the 3D data flow from the CAE directly into production
In the meantime, modern, high-performance CAD/CAE software allows not only realistic plans to be generated in 3D format. The planning data can also be applied to downstream manufacturing and mounting steps with a mouse click. In this, three-dimensional CAE information delivers not only complete parts lists and quantities for the required components. The CAE data also flows into the various production machines. Because the days when industrial workers had to cut cables, drill mounting plates or attach end sleeves are increasingly over. Instead, there are machines to perform those tasks. Fed with data from the planning department, they handle the various routine jobs with a whole new level of precision and speed.

Very high degree of individual automation possible
As a general rule, virtually any mounting step can be automated. It is the panel builder who decides which tasks he would like to perform using a machine – or where he wants to invest in complete automation and where he relies on more economical semi-automation. Let us take the cable harness function, for example: The spectrum ranges from the basic EUR 10,000 machine, which only cuts to size one cable type, right down to the approx. 350,000 high-end automatic machine, which cuts to size all cables for control cabinets of any size – including marking, attachment of end sleeves, bundling, etc.

Machine production is interesting even for smaller panel builders
Especially because the level of automation and the amount of the investment can be decided so individually, production automation is as interesting for large series producers as it is for small panel builders. Add to this the fact that the machine works highly efficiently even starting with single item batches, whereby manufacturers of individual panels and custom machinery can benefit in particular.

Changeover in the preliminary run
Ideally, panel builders and mechanical engineers examine all the opportunities and risks of automated production at an early stage. Important considerations, for example, include a precise analysis of the current engineering and production processes, a comparison of the actual condition with 3D CAE options and a neutral cost-benefit analysis. Whereby the entire changeover time and effort must always be taken into account: from reorganization of the production processes, through the design of an appropriate IT landscape, right down to the qualification of the employees.

Higher productivity, higher quality, greater competitiveness
Independent of how the individual path to automation turns out to be in the end: A machine always works much faster and more precisely than human beings. That is why the use of automated production machines definitely guarantees an edge in productivity, quality and competitiveness. The data-controlled precision of machine production reduces waste and material losses to a minimum. And last but not least, employers can deploy the manufacturing personnel freed up from routine tasks to perform other, more meaningful tasks – an advantage that is extremely important in times of when there is a chronic shortage of skilled labor. Finally, panel builders and mechanical engineers in Germany more and more lament the fact that they can hardly meet the demand with existing personnel. By means of targeted manufacturing automation, production can be significantly increased – with a same workforce.

Skilled workers are assigned new and meaningful tasks
Conversely, however, this also means that the use of highly-efficient machinery does not have to lead to dismissals. An automatic operation, which can suddenly produce 20, instead of five, panels per week, does in fact need each woman and each man – not for cutting cable or drilling mounting plates, however, but for running the machines or maintaining the IT infrastructure. After all, in the scope of automation, a completely new digitalized engineering and manufacturing process is set up.

Component suppliers need to deliver the required product data
And this routine – like every other digital process – is based on large volumes of data. Whereas a two-dimensional CAE system did not need much more than specifications such as height and width per component, with more high-performance CAE tools, it is a whole different story. A modern CAE system, which not only supports three-dimensional planning but also controls the production...
machines, requires much more comprehensive component data, including the electrotechnical information. That is why when choosing products, it is always important to ensure that the manufacturer has equipped its units with all the master data that the CAE system requires. For fully streamlined engineering and production processes, it is also ideal if device and planning tool suppliers work closely together and guarantee fully automated import of product master data by the manufacturer into the CAE.

The following applies in any case: The better the available product master data, the more intelligent the CAE. And the more intelligent the CAE, the more efficiently the gap can be bridged between design and automated manufacturing.
Further information from Siemens!

Siemens provides timely information about the latest developments.

Whether it be reference books, web-based training courses, helpful engineering tools or useful information on all aspects of "panel building". On our Market Portal siemens.com/controlpanel, you’ll find comprehensive information on "Expert know-how, tools and data for digitalization in engineering and a matching product and system portfolio."

Integrated Control Panels – The easy path to the optimal control panel.
